

Table Osm.7

Hierarchical multiple regression analysis with the residual change scores in anti-Semitism as DV testing guilt proneness as a moderator of the interaction between the manipulation of perpetrator (ingroup vs. outgroup) and bogus pipeline condition.

Predictor	<i>B</i>	<i>SE</i>	95% CI	<i>t</i>	<i>p</i>
Constant	-0.04	0.09	[-0.23, 0.14]	-0.47	.639
Step1					
Perpetrator Manipulation (P)	-0.82	0.19	[-1.19, -0.44]	-4.34	< .001
Bogus Pipeline (BP)	-0.01	0.19	[-0.39, 0.36]	-0.06	.950
Guilt Proneness (GP)	0.03	0.10	[-0.16, 0.22]	0.35	.730
Step 2					
P × BP	-0.02	0.38	[-0.77, 0.72]	-0.06	.952
P × GP	0.34	0.19	[-0.04, 0.72]	1.79	.077
BP × GP	-0.28	0.19	[-0.66, 0.10]	-1.47	.146
Step 3					
P × BP × GP	-0.62	0.38	[-1.38, 0.14]	-1.62	.109

Note: Coefficients are taken from the final model, $R^2 = .23$, $F(7, 88) = 3.66$, $p = .002$. We effect coded the experimental factors group membership of the perpetrators (Jewish victims of the ingroup = 0.5, Chinese victims of the outgroup = -0.5) and bogus pipeline (bogus pipeline = 0.5, control = -0.5). Guilt proneness scores were standardized before computing all possible two-way products and the three-way interaction.
